$$\text{Response to } \mathbf{25\%;} \tag{-1}$$

$$\text{This is my corrective action.} \tag{0}$$

1 Overview

1.1 Goal

$$\text{Objective: Build / Compare Two Factor-Based L/S Allocation Models}$$

$$\text{Beta } (\beta) \text{ Constraints}$$

$$\text{First Strategy } (S_{\{1\}}) : \text{Target Beta } \beta_T \in [-0.5, 0.5] \tag{1}$$

$$\text{Second Strategy } (S_{\{2\}}) : \text{Target Beta } \beta_T \in [-2, 2] \tag{2}$$

$$S_{\{1\}} \approxeq \text{Value-at-Risk Utility (Robust Optimization)} \tag{3}$$

$$S_{\{1\}} \Leftarrow \text{Information Ratio} \tag{4}$$

$$\text{Post optimization, I compare model outcomes while evaluating estimator length se}$$

$$[\text{covariance matrix } \mathbf{\Sigma} \wedge \text{expected returns } \boldsymbol{\mu}] \text{ across market regimes} \tag{6}$$

1.2 Reallocation

$$\text{Portfolio Allocation } \{P_t\} \Leftarrow \text{`03-01-2007`} \sim \text{`03-31-2024`} \tag{7}$$

$$P_t \quad \forall\, t \in \{t_0, t_1, t_2, \ldots, t_n\} \quad \text{where} \quad t_0 = \texttt{03-01-2007}, \quad t_n = \texttt{03-31-2024} \tag{8}$$

$$t_i = t_{i-1} + 7 \text{ days} \quad \text{for} \quad i = 1, 2, \ldots, n \tag{9}$$

$$\text{Investment Universe} \equiv \text{ETFs ('Global World Economy')} \tag{10}$$

$$\text{Fama–French Three-Factor Model (Momentum, Value, Size)} \tag{11}$$

$$\text{Public Data} \tag{12}$$

1.3 Performance Evaluation

$$\text{The performance / risk profiles are sensitive to the target Beta and the market en}$$

$$\text{Low Beta} \Rightarrow \text{Decorrelation;} \tag{14}$$

$$\text{High Beta} \equiv \text{Antithesis.} \tag{15}$$

Portfolio Characteristics :

- $$\text{Return} : \mu \tag{16}$$
- $$\text{Volatility (Vol)} : \sigma \tag{17}$$
- $$\text{Skewness (Skew)} : \mathbb{E}\left[\left(\frac{x-\mu}{\sigma}\right)^3\right] = \frac{\mu_3}{\sigma^3} = \frac{\kappa_3}{\kappa_2^{3/2}} \tag{18}$$
- $$\text{Value at Risk (VaR) / Expected Shortfall (ES)} \tag{19}$$
- $$\text{Sharpe Ratio} : \frac{\mathbb{E}[R_a - R_b]}{\sigma_a} = \frac{\mathbb{E}[R_a - R_b]}{\sqrt{\mathbb{V}(R_a - R_b)}} \tag{20}$$

1.4 Simplification

Post Factor Model (FM) construction,

I use trend following estimators for $\boldsymbol{\mu}$.

The estimator quality depends on the look-back (LB) period; $\therefore$

- $$\text{Long-Term Estimator (LTE)} : \text{LT} \Rightarrow \text{LB} \in \{180 \text{ Days}\}. \tag{1}$$
- $$\text{Mid-Term Estimator (MTE)} : \text{MT} \Rightarrow \text{LB} \in \{90 \text{ Days}\}. \tag{2}$$
- $$\text{Short-Term Estimator (STE)} : \text{ST} \Rightarrow \text{LB} \in \{40 \text{ Days}, 60 \text{ Days}\}. \tag{3}$$

Term-Structure for Covariance $\boldsymbol{\Sigma} \ \wedge$ Expected Return $\boldsymbol{\mu}$.

1.5 Synthesis

Optimal portfolio behavior constructed from

covariance and expected return estimators

will vary due to strategic and market differences.

$$S_{40}^{90} \equiv \hat{\boldsymbol{\Sigma}} \Rightarrow 40 \text{ Days} \ \wedge \ \hat{\boldsymbol{\mu}} \Rightarrow 90 \text{ Days} \tag{4}$$

Goal :

- Evaluate Hypothesis
- Demonstrate Robustness (Or Lack Thereof)

- Market Regime Stratification

2 Strategy

Theory \& Math

2.1 Strategic Formulation

Consider two strategies :

$$\text{(Strategy I)} \quad \begin{cases} \max\limits_{\omega \in \mathbb{R}^n} \ \rho^T \omega - \lambda \sqrt{\omega^T \Sigma \omega} \\ -0.5 \leq \sum_{i=1}^n \beta_i^m \omega_i \leq 0.5 \\ \sum_{i=1}^n \omega_i = 1, \quad -2 \leq \omega_i \leq 2, \end{cases} \tag{5}$$

and

$$\text{(Strategy II)} \quad \begin{cases} \max\limits_{\omega \in \mathbb{R}^n} \ \frac{\rho^T \omega}{\text{TEV}(\omega)} - \lambda \sqrt{\omega^T \Sigma \omega} \\ -2 \leq \sum_{i=1}^n \beta_i^m \omega_i \leq 2 \\ \sum_{i=1}^n \omega_i = 1, \quad -2 \leq \omega_i \leq 2, \end{cases} \tag{6}$$

- $\Sigma \equiv$ covariance matrix between security returns (FF3FM);
- $\beta_i^m = \frac{\text{Cov}(r_i, r_M)}{\sigma^2(r_M)} \equiv$ Beta of security S_i (CAPM) s.t.
  $\beta_P^m = \sum_{i=1}^n \beta_i^m \omega_i \equiv$ Porfolio Beta;
- $\text{TEV}(\omega) = \sigma(r_P(\omega) - r_{\text{SPY}}) \equiv$ Tracking Error Volatility;
  trivial derivation (reader exercise) :

$$\sigma(r_P(\omega) - r_{\text{SPY}}) = \sqrt{\omega^\intercal \Sigma \omega - 2\omega^\intercal \text{Cov}(r, r_{\text{SPY}}) + \sigma_{\text{SPY}}^2}. \tag{7}$$

2.2 Fama–French Three-Factor Model (FF3FM)

Definition :

$$r_i = r_f + \beta_i^3 (r_M - r_f) + b_i^s r_{\text{SMB}} + b_i^v r_{\text{HML}} + \alpha_i + \epsilon_i \tag{8}$$

$\mathbb{E}[\epsilon_i] = 0; \therefore$

$$\rho_i = r_f + \beta_i^3(\rho_M - r_f) + b_i^s \rho_{\text{SMB}} + b_i^v \rho_{\text{HML}} + \alpha_i \tag{9}$$

$$\text{Estimated Coefficient Vector :}$$
$$(\hat{\beta}_i^3, \hat{b}_i^s, \hat{b}_i^v)^\intercal \Leftarrow y_i = \rho_i - r_f \tag{10}$$
$$\text{Linear Regression :}$$
$$= \hat{\beta}_i^3(\rho_M - r_f) + \hat{\beta}_i^s r_{\text{SMB}} + \hat{b}_i^v \rho_{\text{HML}} + \epsilon_i \tag{11}$$

$$\beta_i^m \neq \beta_i^3 \mid \text{estimated via separate regression / computed directly.}$$

2.3 Executive Summary Formulation

This section elaborates on the mathematical formulation established in Sections 2.1 but for executives (innumerate):

2.3.1 Strategy I Breakdown

1. **Objective**: Maximize returns while considering risk.

2. **Constraints**:

   - The portfolio's beta must be between -0.5 and 0.5.
   - The sum of the weights assigned to each asset in the portfolio must equal 1.
   - Each individual weight can range from -2 to 2.

2.3.2 Strategy II Breakdown

1. **Objective**: Maximize returns relative to the portfolio's **tracking error volatility** (**TEV**), which measures how much the portfolio's returns deviate from a benchmark.

2. **Constraints**:

   - The portfolio's beta must be between -2 and 2.
   - The sum of the weights assigned to each asset in the portfolio must equal 1.
   - Each individual weight can range from -2 to 2.

The next section establishes the necessary assumptions considered for strategic formulation and implementation.

3 Assumptions and (Analysis) Setup

3.1 Setup

To simplify, we will make the following assumptions for this experiment:

1. The portfolios will be reallocated weekly from the beginning of **March 2007** to the end of **March 2024**.

2. I define three cases:

   - $\text{Long-Term Look-Back Period} : 120\,\text{Data Points}$ for estimation of a $\text{Sample Covariance \& Sample Mean}$; i.e., $\text{Scenario LT} \equiv S_{120}$.
   - $\text{Medium-Term Look-Back Period} : 90\,\text{Data Points}$ for estimation of a $\text{Sample Covariance \& Sample Mean}$; i.e., $\text{Scenario MT} \equiv S_{90}$.
   - $\text{Short-Term Look-Back Period} : 40\,\text{Data Points}$ for estimation of a $\text{Sample Covariance \& Sample Mean}$; i.e., $\text{Scenario ST} \equiv S_{40}$.
3. Consider two possible values for the **Target Beta** (again, ***not*** the colloquial slang term) $: 0 \ \& \ 1$.

4. Consider two possible values for the $\boldsymbol{\lambda}$ (the ***risk aversion parameter***; i.e., how much are you putting on black?) $: 0.10 \ \& \ 0.50$.
